Caries protection...

In kids and teenagers, the enamel is still developing, this is why fixed orthodontic appliances can lead to demineralization around the brace, causing irreversible damage. On the inner surface of the teeth, demineralization is protected against by the permanent action of saliva rinsing and self-cleansing the teeth.

As clinical research has shown, compared to conventional fixed braces, tooth damage in children, is 10 times less likely using a fixed brace bonded on the inner surfaces of the teeth.
